CLAUDE PLUGIN · BITBUCKET · SALESFORCE

Salesforce DevOps, for everyone

Promote changes and keep a clean version history — no senior developer required.

OPFOCUS

Why DevOps has been a weak spot

1

Change sets

Slow, manual, and they overwrite silently — the top way admins break production.

2

The CI/CD push

Salesforce wants everyone on VCS + CI/CD, but the tooling needs a senior developer.

3

Admins locked out

Non-developers can't promote cleanly, so good DevOps never reaches the team.

A Claude plugin that does the heavy lifting

The consultant speaks in plain environment terms — “promote from Dev to Stage.” Claude translates that into the right git and Salesforce CLI steps, under OpFocus guardrails.

Everyone can promote

Admins and devs alike — the judgment is Claude's job.

Clean Bitbucket VCS

Every change captured to git with real history.

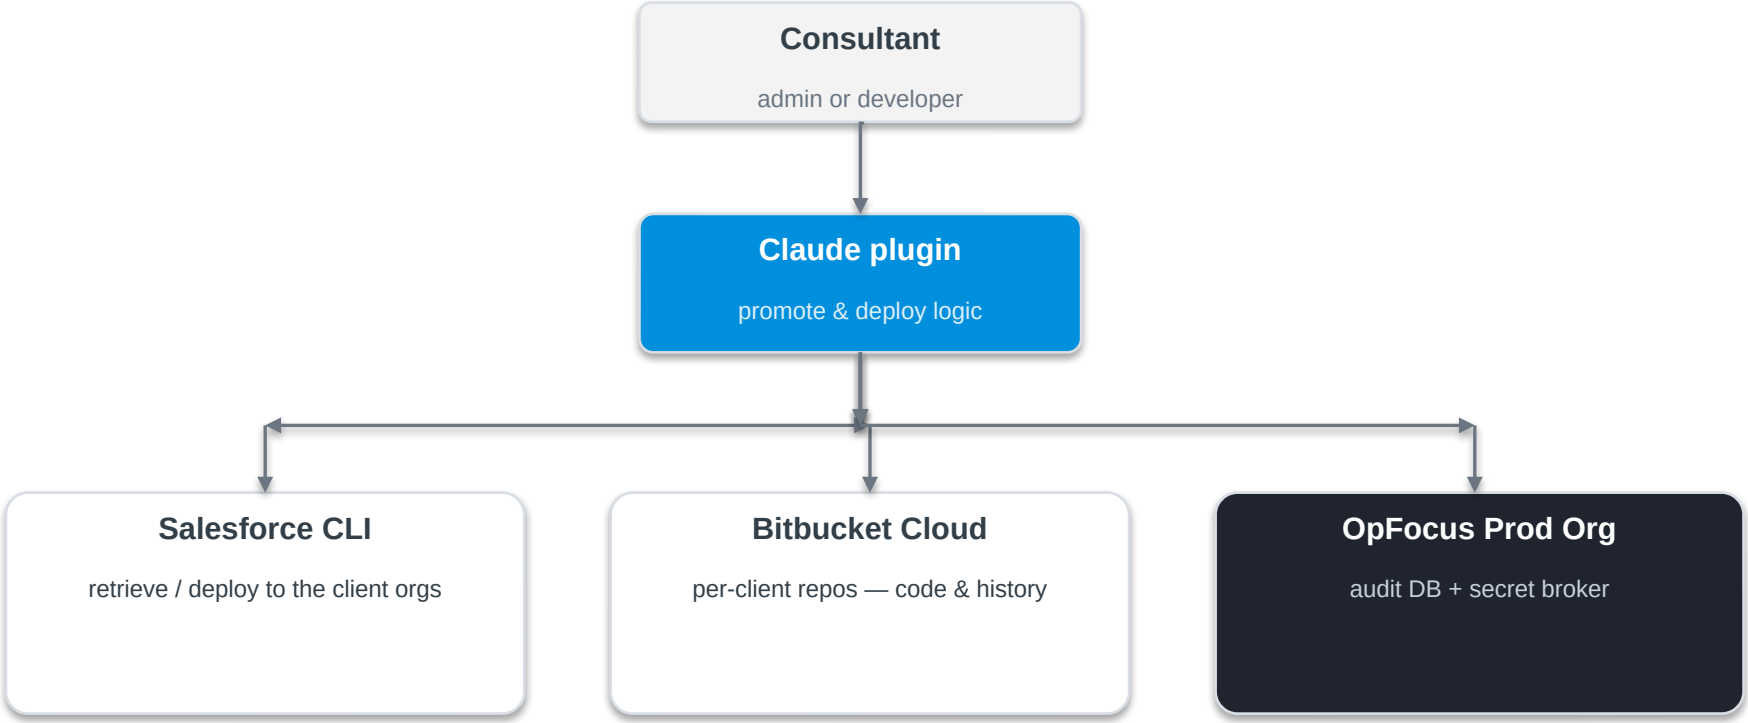

Review with diffs

See exactly what changed — summary plus the line diff.

Shared audit trail

Every promote recorded in Salesforce.

How it fits together

Claude orchestrates the CLI, Bitbucket, and the prod-org database — nothing new to install.

The daily flow: capture → review → promote

1

Capture

Source tracking detects exactly what changed in the org.

2

Review

Every change with a plain-English summary and the line diff.

3

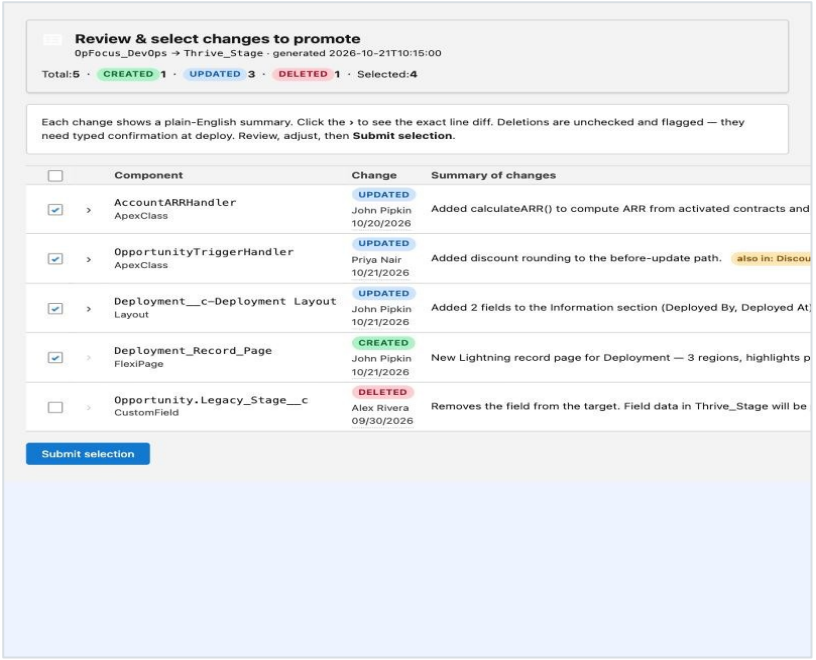

Select

The consultant picks what to promote — nothing added behind their back.

4

Promote

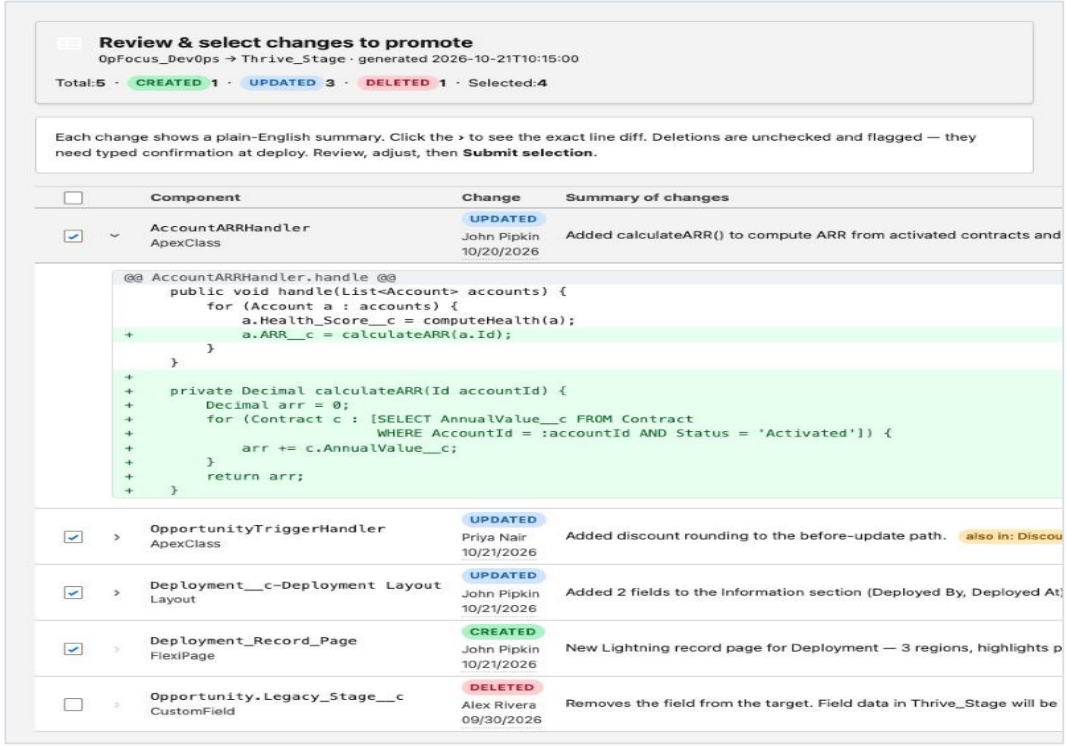

Validate, deploy, commit to the branch, record it.

The review screen — every change, nothing hidden

OPFOCUS

Review every change — with the real diff

Live change-selector — Apex diff expanded

Plain-English summary

Every row, always visible.

Diff on demand

A chevron reveals the exact red/green line diff.

Who & when

Last modified by and date, from the org.

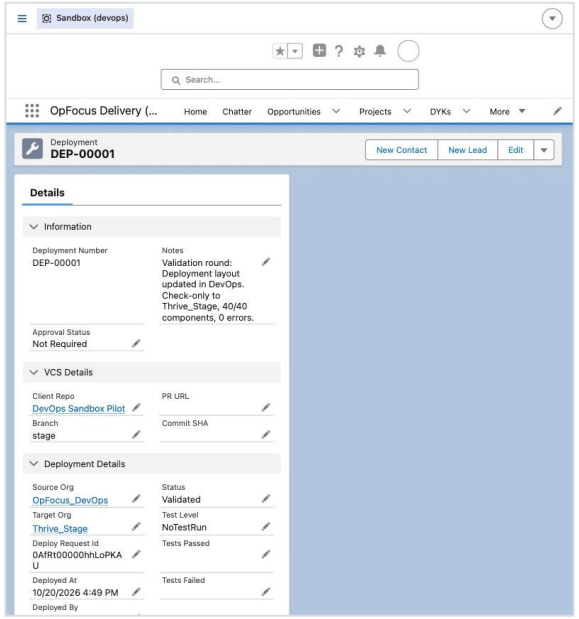

Flags that matter

Shared-initiative and destructive deletes stand out.

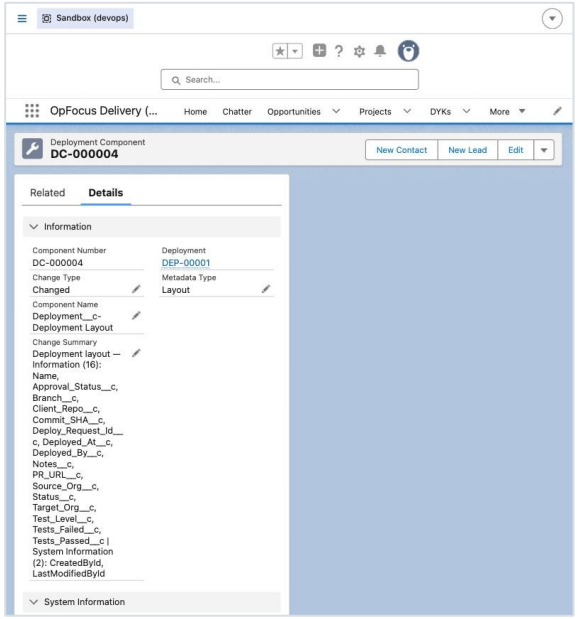

OPFOCUS

Every promote is recorded in Salesforce

The OpFocus production org is the shared database. Each promote writes a Deployment and a child record per component, each with a plain-English change summary.

Deployment record

Component + change summary

Who, what, where

Source/target org, branch, commit, who ran it.

Validated → Deployed

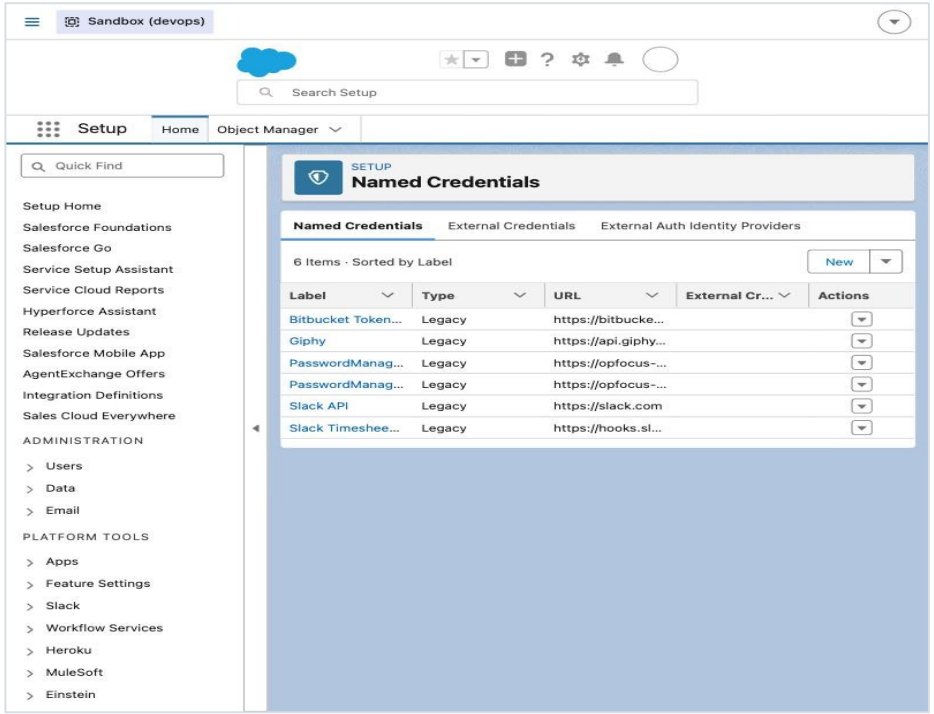

Status lifecycle; tests captured.

Per-component detail

Change type + a summary of what changed.

OPFOCUS

Secrets never touch a laptop

The token-broker Named Credential in Setup

The Bitbucket OAuth secret lives only in a Named Credential in the prod org — encrypted and non-retrievable. An Apex endpoint hands out short-lived tokens. No secret file on any machine.

No secret on laptops

Only disposable 2-hour tokens are vended.

One-step offboarding

Deactivate the user — token access ends.

Rotate in one place

Swap the secret once; everyone keeps working.

OPFOCUS

Guardrails built in

Validate first, always

Check-only before any write — no surprise failures.

Overwrite protection

Warned if the target changed under you.

Deletes need typed confirmation

Destructive changes are off by default.

Profiles excluded

Use permission sets instead — better practice.

Never another team's work

A missing component is flagged, never auto-added.

Default-namespace only

Managed packages & static resources stay out.

Where it stands today

Working end to end

- ✓ Plugin packaged & installable from Bitbucket
- ✓ Backend data model live in the sandbox
- ✓ Source-tracking capture + the review UI
- ✓ Validated dev → stage promote (46 components, 0 errors)
- ✓ Token broker proven — no secret on the laptop

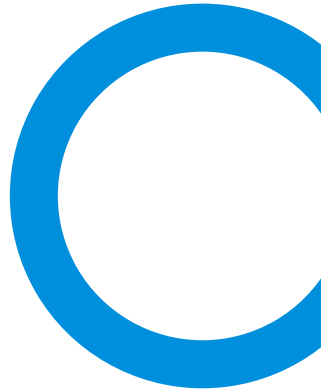

Next

1. Roll the backend + broker to OpFocus Prod
2. Onboard a pilot client repo (CRL)
3. Install for a first group of consultants
4. A real dev → stage deploy, then widen rollout

READY WHEN YOU ARE

Let’s promote something

Install it from Bitbucket, point it at a sandbox, and run a real capture-and-promote.
